(57) **ABSTRACT**

A misplaced item service identifies a plurality of inventory storage locations in a materials handling facility associated with a misplaced item. The misplaced item service determines an ordered list of the plurality of inventory storage locations, wherein the inventory storage locations are arranged in the ordered list based at least in part on a location density of the inventory storage locations, a population density of the inventory storage locations and a last inventory storage location inspected.

PROCESSING OF MISPLACED ITEMS TO RESOLVE INVENTORY DEFECTS

BACKGROUND

Modern inventory systems, such as those in materials handling facilities, distribution warehouses, mail-order warehouses, and custom-order manufacturing facilities, maintain a virtual inventory of items that are supposed to be housed at the facility. The virtual inventory may specify what items are supposed to be present, as well as a specific location within the facility where each item is supposed to be housed. In order to maintain accuracy, the virtual inventory should match a physical inventory of what items are actually housed at the facility, as well as the locations within the facility of where those items are actually housed.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments of the present invention will be understood more fully from the detailed description given below and from the accompanying drawings, which, however, should not be taken to limit the present invention to the specific embodiments, but are for explanation and understanding only.

FIG. 1 is a block diagram illustrating a networked environment in which embodiments of the present invention may be implemented.

FIG. 2 is a block diagram illustrating a misplaced item service, according to an embodiment.

FIG. 3 is a block diagram illustrating an example representation of a materials handling facility, according to an embodiment.

FIG. 4 is a flow diagram illustrating a method for misplaced item processing, according to an embodiment.

FIG. 5 is a flow diagram illustrating a method for misplaced item processing, according to an embodiment.

FIG. 6 is a flow diagram illustrating a method for bin grouping, according to an embodiment.

FIG. 7 is a flow diagram illustrating a method for ordered list generation, according to an embodiment.

FIG. 8 is a block diagram illustrating an exemplary computer system, according to an embodiment.

DETAILED DESCRIPTION

Materials handling facilities such as warehouses often struggle to keep track of inventory accurately. A significant contributor to this struggle is the need to process misplaced items. The materials handling facility may maintain a virtual inventory of the inventory storage locations for each item or type of items. Generally, this virtual inventory can be relied on to accurately reflect the physical inventory and allow materials handling facility associates to locate particular items within the facility. In certain situations, however, an inventory item may be misplaced, thereby rendering the virtual inventory inaccurate. For example, if an item falls off a shelf, is dropped during transport, or is otherwise misplaced, the proper storage bin in the materials handling facility may not be readily apparent.

In one embodiment, a misplaced item service may be executed to generate an ordered list of potential item storage bins for a misplaced item which can be inspected by a materials handling facility associate to determine if the potential item storage bins are the actual bins to which the misplaced item can be returned. The potential item storage bins may be arranged in the ordered list in such a way so as to improve the

2

probability of finding the correct storage bin for the misplaced item and to optimize a transit time between the potential items storage bins for the materials handling facility associate in order to improve the efficiency with which the proper item storage bin is determined.

In one embodiment, the misplaced item service receives an indication of a location of a misplaced item bin within a materials handling facility. The materials handling facility may include a plurality of bins including the misplaced item bin and a plurality of item storage bins. The misplaced item service may receive an indication of a misplaced item that was inadvertently removed from one of the plurality of item storage bins and placed in the misplaced item bin. The misplaced item service may identify a group of potential item storage bins that are each located within a threshold distance of the location of the misplaced item bin. In one embodiment, a virtual inventory of the materials handling facility indicates that each potential item storage bin in the group comprises one or more items having a same item type as the misplaced item. From the group of potential bins, the misplaced item bin determines an ordered list of potential item storage bins from the group of potential bins, where the potential item storage bins on the ordered list are arranged in an order to optimize a transit time between the potential item storage bins in the materials handling facility for a materials handling facility associate. The misplaced item service provides the ordered list to a client device corresponding to the materials handling facility associate, so that the associate can inspect the relevant bins to determine where the misplaced item belongs.

FIG. 1 is a block diagram illustrating a networked environment for processing misplaced items to resolve physical inventory, according to an embodiment. The networked environment **100** includes a computing environment **101** and one or more client devices **130**, which are in data communication with each other via a network **140**. The network **140** includes, for example, the Internet, intranets, extranets, wide area networks (WANs), local area networks (LANs), wired networks, wireless networks, or other suitable networks, etc., or any combination of two or more such networks. For example, such networks may comprise satellite networks, cable networks, Ethernet networks, and other types of networks.

The computing environment **101** may include, for example, a server computer or any other system providing computing capability. Alternatively, the computing environment **101** may employ a plurality of computing devices that may be arranged, for example, in one or more server banks or computer banks or other arrangements. Such computing devices may be located in a single installation or may be distributed among many different geographical locations. For example, the computing environment **101** may include a plurality of computing devices that together may comprise a hosted computing resource, a grid computing resource and/or any other distributed computing arrangement. In some cases, the computing environment **101** may correspond to an elastic computing resource where the allotted capacity of processing, network, storage, or other computing-related resources may vary over time.

Various applications and/or other functionality may be executed in the computing environment **101** according to various implementations. Also, various data may be stored in a data store **120** that is accessible to the computing environment **101**. The data store **120** may be representative of a plurality of data stores, as can be appreciated. The data stored in the data store **120**, for example, is associated with the operation of the various applications and/or functional entities described below.

The components executed on the computing environment **101**, for example, can include a misplaced item service **110**, and other applications, services, processes, systems, engines, or functionality not discussed in detail herein. The misplaced item service **110** may be executed to generate an ordered list of potential item storage bins for a misplaced item which can be inspected by a materials handling facility associate to determine if the potential item storage bins are the actual bins to which the misplaced item can be returned. The potential item storage bins may be arranged in the ordered list in such a way so as to optimize a transit time between the potential items storage bins for the materials handling facility associate in order to improve the efficiency with which the proper item storage bin is determined. In one embodiment, the transit time may be the time that it takes a person to walk between potential item storage bins. In other embodiments, the transit time may represent any amount of time that it takes a person, robot or other device to travel in any variety of ways between the locations of the potential item storage bins. Additional details of misplaced item service **110** are provided below.

Client devices **130** are representative of a plurality of client devices that may be coupled to the network **140**. The client devices **130** may each comprise, for example, a processor-based system such as a computer system. Such a computer system may be embodied in the form of a desktop computer, a laptop computer, personal digital assistants, cellular telephones, smartphones, set-top boxes, music players, web pads, tablet computer systems, game consoles, electronic book readers, or other devices with similar capability. In one embodiment, the client devices **130** may each include a scanner **132** and a locator tool **134**. Scanner **132** may be a barcode scanner, quick response (QR) code scanner, radio frequency identification (RFID) chip reader, charge-coupled device (CCD) reader, camera or some other type of scanner that can be used to identify a specific bin or inventory storage location in the materials handling facility. For example, each bin in the materials handling facility may be identified using a barcode, RFID chip or other machine-readable representation of data. Scanner **132** may be used to read the barcode and convey the identity of the scanned bin to locator tool **134** on client device **130**.

The client devices **130** may be configured to execute various applications such as locator tool **134** and/or other applications. The locator tool **134** may be an application or other program that is executed on a client device **130**, for example, to access network content served up by the computing environment **101** and/or other servers. To this end, the locator tool **134** may include, for example, a browser, a dedicated application, etc. The client devices **130** may be configured to execute applications beyond the locator tool **134** such as, for example, email applications, social networking applications, word processors, spreadsheets, or other applications. The locator tool **134** may provide a user interface on a display of the client device **130**. The display may include, for example, one or more devices such as liquid crystal displays (LCDs), gas plasma-based flat panel displays, organic light emitting diode (OLED) displays, electrophoretic ink (E ink) displays, LCD projectors, or other types of display devices, etc. In one embodiment, locator tool **134** provides the identity of the scanned bin to misplaced item service **110**. In response, locator tool **134** may receive an indication of one or more potential item storage bins to be inspected for determination of whether they correspond to the misplaced item. Additional details of locator tool **134** are provided below.

FIG. 2 is a block diagram illustrating a misplaced item service **110** that is included in computing environment **101**, according to an embodiment. In one embodiment, misplaced

item service **110** includes client device interface module **202**, bin grouping module **204** and list ordering module **206**. This arrangement of modules and components may be a logical separation, and in other embodiments, these modules or other components can be combined together or separated in further components, according to a particular embodiment. In one embodiment, data store **120** is connected to misplaced item service **110** and includes bin inventory data **222**, bin group data **224** and ordered list data **226**. In one embodiment computing environment **101** may include both misplaced item service **110** and data store **120**. In another embodiment, data store **120** may be external to computing environment **101** and may be connected to computing environment **101** over a network or other connection. In other embodiments, misplaced item service **110** may include different and/or additional components which are not shown to simplify the description. Data store **120** may include one or more mass storage devices which can include, for example, flash memory, magnetic or optical disks, or tape drives; read-only memory (ROM); random-access memory (RAM); erasable programmable memory (e.g., EPROM and EEPROM); flash memory; or any other type of storage medium.

In one embodiment, client device interface module **202** is responsible for communication and interaction with locator tool **134** on client device **130**. In one embodiment, client device interface module **202** receives information sent from locator tool **134**, such as information obtained using scanner **132**. For example, client device interface module **202** may receive an indication of a location of a misplaced item bin or item storage bin within the materials handling facility. A materials handling facility associate may scan a barcode or other indicator on the bin using scanner **132** and locator tool **134** may provide an indication of the bin to client device interface module **202**. In one embodiment, the received information may also include an indication of the location of the bin (which may be stored in the scanned barcode) or misplaced item service **110** may consult bin inventory data **222** in data store **120** to look up the location of the bin. In another embodiment, client device interface module **202** may receive an indication of the misplaced item from client device **130**. For example, the materials handling facility associate may scan a barcode or other indicator on the misplaced item itself using scanner **132** and locator tool **134** may provide an indication of the misplaced item to client device interface module **202**. In another embodiment, client device interface module **202** may provide an ordered list of potential item storage bins to locator tool **134**. The materials handling facility associate may inspect the bins in the order they are listed in order to locate the bin where the misplaced item belongs. In another embodiment, client device interface module **202** may provide an indication of one potential item storage bin at a time to locator tool **134**. Client device interface module **202** may receive a result of the inspection of that bin, and if the inspected bin was not the correct bin, may provide a next potential item storage bin to locator tool **134** for inspection.

In one embodiment, bin grouping module **204** identifies a group of potential item storage bins that may include the bin to which the misplaced item belongs. In one embodiment, bin grouping module **204** identifies all of the bins that are supposed to contain items of the same item type as the misplaced item. For example, bin grouping module **204** may consult bin inventory data **222** to identify the bins. Bin inventory data **222** may include an entry for each bin or other inventory storage location in the materials handling facility and may include an indication of what item types and how many of each item are supposed to be stored in the bin. Alternatively, bin inventory data **222** may be indexed by item type, with an entry for each

5

item, and an indication of in which bins items of that type are supposed to be stored. In addition, bin grouping module **204** may group the potential bins by their respective distance from the misplaced item bin. In one embodiment, bin grouping module **204** may identify the location of each potential bin as well as the location of the misplaced item bin. The location of each bin may be stored in the corresponding entry in bin inventory data **222**. Bin grouping module **204** may calculate the distance between each potential item storage bin and the misplaced item bin. This distance may be expressed in terms of standard units, such as feet or meters, or as a relative value expressed in terms of the locations in the materials handling facility, such as in a number of aisles, a number of bins, a number of floors, or using some other unit of measurement. Bin grouping module **204** may group the bins based on their distances from the misplaced item bin. In one embodiment, a number of thresholds or group boundaries may be established for the groups. For example, the group boundaries may be less than three aisles, three to six aisles, and six or more aisles. Bin grouping module **204** may place each potential item storage bin in a group according to these boundaries. In other embodiments, there may be some other number of bin groups and different or additional group boundaries may be used. Bin grouping module **204** may store the resulting bin groups as bin group data **224** in data store **120**.

In one embodiment, list ordering module **206** determines an ordered list of potential item storage bins from a group of bins identified by bin grouping module **204**. For example, list ordering module **206** may arrange the bins in a first group (e.g., within three aisles of the misplaced item bin in the materials handling facility) in an order to optimize a transit time between the potential items storage bins for the materials handling facility associate in order to improve the efficiency with which the proper item storage bin is determined. In one embodiment, list ordering module **206** assigns a weighting value to each of the potential item storage bins in the group and orders the bins from the highest weight to the lowest. In an alternative embodiment where a lower weight is indicative of higher preference, the bins may be ordered from the lowest weight to the highest. The weighting value may be determined for each potential item storage bin according to a number of factors. In one embodiment, the weighting value may be determined based at least in part on a bin location density of the potential item storage bin, a bin population density of the potential item storage bin and a last potential item storage bin inspected by the materials handling facility associate. These factors may be combined to determine the weighting value of each bin. In one embodiment, the weighting values represent the likelihood that the misplaced item belongs to a corresponding potential item storage bin. List ordering module **206** may store the resulting list as ordered list data **226**. In one embodiment, the ordered list data **226** is statically created. For example, list ordering module **206** creates the ordered list **226** and the ordered list **226** does not change based on the result of any bin inspections by the materials handling facility associate. The materials handling facility associate may inspect each bin on the ordered list **226**, in the original order **226**, until the correct bin is located. In another embodiment, the ordered list data **226** is dynamically updated. Based on the result of each bin inspection by the materials handling facility associate, list ordering module **206** may recalculate the ordered list **226** using the results of the bin inspection, the location of the last bin inspected, and other factors. In this manner, the ordered list **226** may change over time from the originally determined order.

FIG. 3 is a block diagram illustrating an example representation of a materials handling facility **300**, according to an

6

embodiment. The materials handling facility **300** may include, for example, a warehouse, storage unit, fulfillment center, or other facility and represents any appropriate facility for storing, distributing, and/or selling inventory items. Materials handling facility **300** may receive shipping containers of inventory items at various times, store the inventory items for a period of time and ship the inventory items out in response to receiving orders for the items.

Materials handling facility **300** may include various inventory holders **330** arranged according to a particular layout. As illustrated, the layout of inventory holders **330** of materials handling facility **300** is arranged in aisles **92a** to **92f**. Each aisle **92** of inventory holders **330** may hold various types of inventory items. Aisles **92** may be divided into sections, with each section holding one or more particular subtypes of inventory items. For example, materials handling facility may store various goods for consumer purchase on shelves arranged into aisles **92**. Goods may be arranged by type and various subtypes in a manner typical to such facilities. It should be noted that while materials handling facility **300** is illustrated as including aisles **92** having sections of a particular layout and geometry, it is contemplated that materials handling facility **300** may have any appropriate layout and geometry. Moreover, while a specific illustration has been provided by way of example, the concepts of the present disclosure may apply to any number and/or types of facilities storing various types and categories of inventory items. Accordingly, while facility **300** is illustrated as arranging inventory items into aisles **92**, facility **300** may be arranged in any appropriate layout having any appropriate arrangements and/or geometries of inventory items within inventory holders **330**. Inventory holders **330** can represent any appropriate form of container into or onto which inventory items can be placed for storage, shipping, or other appropriate purposes. Examples of inventory holders **330** include, but are not limited to, shelves, boxes, pallets, bins, totes, cartons, etc. In another embodiment, inventory holders **330** can represent an inventory storage location within materials handling facility **300**, such as a location on a shelf on an aisle. For ease of discussion, in the following description, inventory holders **330** are referred to as item storage bins **330**.

Materials handling facility **300** may include one or more designated misplaced item bins **332a-332b**. These misplaced item bins **332** may be bins or inventory storage locations that are not generally used to store inventory items, but rather are used to temporarily store misplaced items before those items can be returned to their proper item storage bins, e.g., **334a-334j**. For example, if an item falls off a shelf, is dropped during transport, or is otherwise misplaced, the proper storage bin **330** may not be readily apparent. As a result, the misplaced item may be placed in the misplaced item bin **332** for processing. A materials handling facility associate may retrieve the misplaced item from one of misplaced item bins **332a-332b** and inspect item storage bins **334a-334j** according to an ordered list provided by misplaced item service **110** in order to find the proper storage bin. In different embodiments, misplaced item bins **332** may be located at different locations throughout materials handling facility **300**. For example, a misplaced item bin **332** may be located on each aisle **92** or there may only be one misplaced item bin **332** per several aisles. On aisles that have a misplaced item bin **332**, the misplaced item bins **332** may each be located in the same location (e.g., on the end of the aisle) or the misplaced item bins **332** may be located at different locations on each aisle. Additional details of materials handling facility **300** are provided below.

FIG. 4 is a flow diagram illustrating a method for misplaced item processing, according to an embodiment. The method 400 may be performed by processing logic that comprises hardware (e.g., circuitry, dedicated logic, programmable logic, microcode, etc.), software (e.g., instructions run on a processor to perform hardware simulation), firmware, or a combination thereof. The processing logic is configured to generate an ordered list of potential item storage bins for a misplaced item in order to optimize a transit time between the potential item storage bins for a materials handling facility associate. In one embodiment, method 400 may be performed by misplaced item service 110, as shown in FIGS. 1 and 2.

Referring to FIG. 4, at block 410, method 400 receives an indication of a location of a misplaced item bin within a materials handling facility. In one embodiment, client device interface module 202 may receive an indication of a location of a misplaced item bin 332b within the materials handling facility 300. A materials handling facility associate may scan a barcode or other indicator on the bin using scanner 132 and locator tool 134 may provide an indication of the bin to client device interface module 202. In one embodiment, the received information may also include an indication of the location of the bin (which may be stored in the scanned barcode) or misplaced item service 110 may consult bin inventory data 222 in data store 120 to look up the location of the bin. In one embodiment, the misplaced item bin may not have a defined location within the materials handling facility (e.g., may be a movable bin) or may not have a barcode or other indicator that is able to be scanned. In this case, the associate may scan the nearest item storage bin to where the misplaced item bin is currently located and use the location of that item storage bin as the effective location of the misplaced item bin.

At block 420, method 400 receives an indication of a misplaced item. In one embodiment, the misplaced item may have been inadvertently removed from one of the plurality of item storage bins in the materials handling facility and placed into the misplaced item bin. In one embodiment, client device interface module 202 may receive an indication of the misplaced item from client device 130. For example, the materials handling facility associate may scan a barcode or other indicator on the misplaced item itself using scanner 132 and locator tool 134 may provide an indication of the misplaced item to client device interface module 202.

At block 430, method 400 identifies a group of potential item storage bins within a threshold distance of the location of the misplaced item bin. In one embodiment, a virtual inventory of the materials handling facility indicates that each potential item storage bin comprises one or more items having a same item type as the misplaced item. In one embodiment, bin grouping module 204 identifies a group of potential item storage bins 334a-334j that may include the bin to which the misplaced item belongs. In one embodiment, bin grouping module 204 identifies all of the bins that are supposed to contain items of the same item type as the misplaced item. For example, bin grouping module 204 may consult bin inventory data 222 to identify the bins. In one embodiment, bin grouping module 204 may identify the location of each potential bin 334a-334j as well as the location of the misplaced item bin 332b. Bin grouping module 204 may calculate the distance between each potential item storage bin and the misplaced item bin. Bin grouping module 204 may group the bins based on their distances from the misplaced item bin and store the resulting bin groups as bin group data 224 in data store 120. Additional details of bin grouping are described below with respect to FIG. 6.

At block 440, method 400 determines an ordered list of potential item storage bins from the group of potential item storage bins. In one embodiment, the potential item storage bins on the list are arranged in an order to optimize a transit time between the potential item storage bins for a materials handling facility associate. In one embodiment, list ordering module 206 determines an ordered list of potential item storage bins from a group of bins identified by bin grouping module 204. For example, list ordering module 206 may arrange the bins in a first group (e.g., within three aisles of the misplaced item bin in the materials handling facility) in an order to optimize a transit time between the potential item storage bins for the materials handling facility associate in order to improve the efficiency with which the proper item storage bin is determined. In one embodiment, list ordering module 206 assigns a weighting value to each of the potential item storage bins in the group and orders the bins from the highest weight to the lowest. In one embodiment, the weighting value may be determined based at least in part on a bin location density of the potential item storage bin, a bin population density of the potential item storage bin and a last potential item storage bin inspected by the materials handling facility associate. List ordering module 206 may store the resulting list as ordered list data 226. Additional details of list ordering are described below with respect to FIG. 7.

At block 450, method 400 provides the ordered list to a client device corresponding to the materials handling facility associate. In one embodiment, client device interface module 202 may provide an ordered list of potential item storage bins to locator tool 134. The materials handling facility associate may inspect the bins in the order they are listed in order to locate the bin where the misplaced item belongs.

FIG. 5 is a flow diagram illustrating a method for misplaced item processing, according to an embodiment. The method 500 may be performed by processing logic that comprises hardware (e.g., circuitry, dedicated logic, programmable logic, microcode, etc.), software (e.g., instructions run on a processor to perform hardware simulation), firmware, or a combination thereof. The processing logic is configured to generate an ordered list of potential item storage bins for a misplaced item in order to optimize a transit time between the potential item storage bins for a materials handling facility associate. In one embodiment, method 500 may be performed by misplaced item service 110, as shown in FIGS. 1 and 2.

Referring to FIG. 5, at block 510, method 500 provides an indication of a first potential item storage bin from the ordered list to the client device. In one embodiment, the first potential item storage bin may be the bin with the highest weighting value. In other embodiments, the first potential item storage bin may be some other bin on the ordered list.

At block 520, method 500 receives a result of an inspection of the first potential item storage bin by the materials handling facility associate. In one embodiment, the inspection comprises comparing an actual number of items having the same item type as the misplaced item that are present in the potential item storage bin to a number of items indicated in the virtual inventory for the potential item storage bin.

At block 530, method 500 determines whether the misplaced item belonged in the inspected bin. In one embodiment, the misplaced item belongs in the bin if the physical inventory of the bin mismatches the virtual inventory bin by one item of the same type of the misplaced item. For example, if the misplaced item is a widget, and the virtual inventory for the potential item storage bin indicates that there should be ten widgets in the bin, but the inspection by the associate reveals that there are actually only nine widgets in the bin, the misplaced widget belongs to that bin. If the physical inven-

tory of the bin matches the virtual inventory of the bin, then the misplaced item does not belong to that bin.

At block **540**, method **500** dynamically updates the ordered list of potential item storage bins. Based on the result of the bin inspection (i.e., whether or not the misplaced item belonged to the first potential item storage bin), list ordering module **206** can dynamically update the list. In one embodiment, dynamically updating the ordered list includes recalculating the weighting values for each of the potential item storage bins. During the recalculation, one or more of the factors may be reconsidered, such as the bin location density of the potential item storage bin, the bin population density of the potential item storage bin and the last potential item storage bin inspected by the materials handling facility associate.

At block **550**, method **500** provides an indication of the next potential item storage bin from the updated list to the client device. In one embodiment, the next potential item storage bin may be the bin with the highest weighting value. In other embodiments, the next potential item storage bin may be some other bin on the ordered list.

FIG. **6** is a flow diagram illustrating a method for bin grouping, according to an embodiment. The method **600** may be performed by processing logic that comprises hardware (e.g., circuitry, dedicated logic, programmable logic, microcode, etc.), software (e.g., instructions run on a processor to perform hardware simulation), firmware, or a combination thereof. The processing logic is configured to identify a group of potential item storage bins for a misplaced item, where each potential item storage bin in the group is within a threshold distance from the location of the misplaced item bin. In one embodiment, method **600** may be performed by misplaced item service **110**, as shown in FIGS. **1** and **2**.

Referring to FIG. **6**, at block **610**, method **600** identifies a plurality of item storage bins that are supposed to contain the type of misplaced item. In one embodiment, bin inventory data **222** indicates the presence of one or more items having a same item type as the misplaced item in the potential item storage bins **334a-334j**. In one embodiment, bin grouping module **204** may consult bin inventory data **222** to identify the bins. Bin inventory data **222** may include an entry for each bin or other inventory storage location in the materials handling facility and may include an indication of what item types and how many of each item are supposed to be stored in the bin. Alternatively, bin inventory data **222** may be indexed by item type, with an entry for each item, and an indication of in which bins items of that type are supposed to be stored.

At block **620**, method **600** identifies a location of each potential item storage bin. In one embodiment, bin grouping module **204** may identify the location of each potential bin as well as the location of the misplaced item bin. The location of each bin may be stored in the corresponding entry in bin inventory data **222**.

At block **630**, method **600** calculates a distance between each potential item storage bin and the misplaced item bin. Bin grouping module **204** may calculate the distance between each potential item storage bin **334a-334j** and the misplaced item bin **332b**. This distance may be expressed in terms of standard units, such as feet or meters, or as a relative value expressed in terms of the locations in the materials handling facility, such as in a number of aisles, a number of bins, a number of floors, or using some other unit of measurement.

At block **640**, method **600** determines whether the distance for a given item storage bin is within the boundaries for a first group. In one embodiment, a number of thresholds or group boundaries may be established for the groups. For example, the group boundaries may be less than three aisles, three to six

aisles, and six or more aisles. Bin grouping module **204** may place each potential item storage bin in a group according to these boundaries. If the distance is within the boundaries for the first group, at block **650**, method **600** adds the item storage bin to the first group by storing an indication of the bin in bin group data **224**. If the distance is not within the boundaries for the first group, at block **660**, method **600** determines whether the distance for a given item storage bin is within the boundaries for a second group (e.g., three to six aisles). If the distance is within the boundaries for the second group, at block **670**, method **600** adds the item storage bin to the second group. If the distance is not within the boundaries for the second group, at block **680**, method **600** adds the item storage bin to a third group. In other embodiments, there may be some other number of bin groups and different or additional group boundaries may be used.

FIG. **7** is a flow diagram illustrating a method for ordered list generation, according to an embodiment. The method **700** may be performed by processing logic that comprises hardware (e.g., circuitry, dedicated logic, programmable logic, microcode, etc.), software (e.g., instructions run on a processor to perform hardware simulation), firmware, or a combination thereof. The processing logic is configured to generate an ordered list of potential item storage bins for a misplaced item in order to optimize a transit time between the potential item storage bins for a materials handling facility associate. In one embodiment, method **700** may be performed by misplaced item service **110**, as shown in FIGS. **1** and **2**.

Referring to FIG. **7**, at block **705**, method **700** identifies a location of each bin in a group of potential item storage bins. In one embodiment, list ordering module **206** may identify the location of each potential bin. The location of each bin may be stored in the corresponding entry in bin inventory data **222**.

At block **710**, method **700** determines whether a given bin is part of a dense cluster of bins. In one embodiment, list ordering module **206** may use a defined cluster radius and cluster threshold to determine whether the bin is part of a cluster. The cluster radius may represent a distance (e.g., one aisle, $\frac{1}{2}$ an aisle) and the cluster threshold may represent a number of other potential item storage bins within the cluster radius distance from the given bin. Referring to FIG. **3** for example, if the cluster radius is one aisle and the cluster threshold is three bins, potential item storage bins **334e**, **334f** and **334g** would meet the criteria for a cluster on aisle **92d**. There are no other bins in materials handling facility **300** that have at least three potential item storage bins **334** within the same aisle **92**.

If the given bin is part of a dense cluster of bins, at block **715**, method **700** increases the bin weighting value for the bin. In one embodiment, list ordering module **206** may increase the weighting value by a fixed amount (e.g., one unit) for each of the bins in the cluster **334e-334g**. In another embodiment, list ordering module **206** may increase the weighting value by a variable amount depending on the density of the cluster. For example, since there are three bins in the cluster, the weighting value for each bin may be increased by three units. If there were four bins in the cluster, the weighting value may be increased by four units and so on. In other embodiments, the weighting value may be adjusted by some other amount. By increasing the weighting value of bins in a dense cluster, list ordering module **206** increases the priority of those bins in the ordered list. This may be advantageous because when multiple bins are located physically close to one another, it is quick and easy for a materials handling facility associate to inspect each of those bins in succession. This can increase the efficiency of finding the proper item storage bin for the mis-

11

placed item. If the given bin is not part of a dense cluster of bins, at block **720**, method **700** decreases the bin weighting value for the bin. In another embodiment, method **700** may keep the bin weighting value constant rather than decreasing the value.

At block **725**, method **700** identifies the number of items in each item storage bin in the group of potential item storage bins. In one embodiment, list ordering module **206** consults bin inventory data **222** to determine the number of items that are supposed to be stored in each bin according to the virtual inventory.

At block **730**, method **700** determines whether the number of items in a given bin is below a bin threshold. In one embodiment, list ordering module **206** may compare the number of items in the bin to the threshold. The threshold may be a configurable value that is the same for every bin regardless of the type of items stored therein or that is specific to each individual bin and is set with respect to the type of items stored therein.

If the number of items in the given bin is below or equal to the bin threshold, at block **735**, method **700** increases the bin weighting value for the bin. In one embodiment, list ordering module **206** may increase the weighting value by a fixed amount (e.g., one unit) for each of the bins that fall below the bin threshold. In another embodiment, list ordering module **206** may increase the weighting value by a variable amount depending on the density of the bin. For example, the more that the number of items in the bin is below the threshold, the higher the bin weighting value may be. In other embodiments, the weighting value may be adjusted by some other amount. By increasing the weighting value of bins that are less densely packed, list ordering module **206** increases the priority of those bins in the ordered list. This may be advantageous because when bins are less densely packed (i.e., there are fewer items stored in the bin), it is quick and easy for a materials handling facility associate to inspect each of those bins. This can increase the efficiency of finding the proper item storage bin for the misplaced item. If the number of items in the given bin is above the bin threshold, at block **740**, method **700** decreases the bin weighting value for the bin. In another embodiment, method **700** may keep the bin weighting value constant rather than decreasing the value.

At block **745**, method **700** calculates the distance between a given potential bin and the last bin inspected by the materials handling facility associate. List ordering module **206** may calculate the distance between each potential item storage bin **334a-334j** and the last bin inspected by the associate. This distance may be expressed in terms of standard units, such as feet or meters, or as a relative value expressed in terms of the locations in the materials handling facility, such as in a number of aisles, a number of bins, a number of floors, or using some other unit of measurement. An indication of the location of the last bin inspected may be received from client device **130** and stored by misplaced item service **110** in data store **120**. In the event that no potential item storage bin has yet been inspected, list ordering module **206** may use the location of the misplaced item bin **332b**.

At block **750**, method **700** determines whether the distance determined at block **745** is below a distance threshold. In one embodiment, list ordering module **206** may compare the distance to the threshold. The threshold may be a configurable value that is the same for every bin or that is specific to each individual bin.

If the distance between the given potential bin and the last bin inspected is below or equal to the distance threshold, at block **755**, method **700** increases the bin weighting value for the bin. In one embodiment, list ordering module **206** may

12

increase the weighting value by a fixed amount (e.g., one unit) for each of the bins that fall below the distance threshold. In another embodiment, list ordering module **206** may increase the weighting value by a variable amount depending on the actual distance from the last bin inspected. For example, the more that the distance is below the threshold, the higher the bin weighting value may be. In other embodiments, the weighting value may be adjusted by some other amount. By increasing the weighting value of bins that are located near the last bin inspected (which is presumably where the materials handling facility associate is still located), list ordering module **206** increases the priority of those bins in the ordered list. This may be advantageous because when the next bin to be inspected is located close to the last bin that was inspected, it is quick and easy for the materials handling facility associate to walk to the next bin. This can increase the efficiency of finding the proper item storage bin for the misplaced item. If the distance between the given potential bin and the last bin inspected is above the distance threshold, at block **760**, method **700** decreases the bin weighting value for the bin. In another embodiment, method **700** may keep the bin weighting value constant rather than decreasing the value.

FIG. **8** illustrates a diagrammatic representation of a machine in the exemplary form of a computer system **800** within which a set of instructions, for causing the machine to perform any one or more of the methodologies discussed herein, may be executed. The system **800** may be in the form of a computer system within which a set of instructions, for causing the machine to perform any one or more of the methodologies discussed herein, may be executed. In alternative embodiments, the machine may be connected (e.g., networked) to other machines in a LAN, an intranet, an extranet, or the Internet. The machine may operate in the capacity of a server machine in client-server network environment. The machine may be a personal computer (PC), a set-top box (STB), a server, a network router, switch or bridge, or any machine capable of executing a set of instructions (sequential or otherwise) that specify actions to be taken by that machine. Further, while only a single machine is illustrated, the term "machine" shall also be taken to include any collection of machines that individually or jointly execute a set (or multiple sets) of instructions to perform any one or more of the methodologies discussed herein. In one embodiment, computer system **800** may represent computing environment **101** of FIG. **1**.

The exemplary computer system **800** includes a processing device (processor) **802**, a main memory **804** (e.g., read-only memory (ROM), flash memory, dynamic random access memory (DRAM) such as synchronous DRAM (SDRAM)), a static memory **806** (e.g., flash memory, static random access memory (SRAM)), and a data storage device **818**, which communicate with each other via a bus **830**.

Processing device **802** represents one or more general-purpose processing devices such as a microprocessor, central processing unit, or the like. More particularly, the processing device **802** may be a complex instruction set computing (CISC) microprocessor, reduced instruction set computing (RISC) microprocessor, very long instruction word (VLIW) microprocessor, or a processor implementing other instruction sets or processors implementing a combination of instruction sets. The processing device **802** may also be one or more special-purpose processing devices such as an application specific integrated circuit (ASIC), a field programmable gate array (FPGA), a digital signal processor (DSP), network processor, or the like. The processing device **802** is configured to execute the processing logic **826** for performing the operations and steps discussed herein.

13

The computer system **800** may further include a network interface device **808**. The computer system **800** also may include a video display unit **810** (e.g., a liquid crystal display (LCD) or a cathode ray tube (CRT)), an alphanumeric input device **812** (e.g., a keyboard), a cursor control device **814** (e.g., a mouse), and a signal generation device **816** (e.g., a speaker).

The data storage device **818** may include a computer-readable medium **828** on which is stored one or more sets of instructions **822** (e.g., instructions of misplaced item service **110**) embodying any one or more of the methodologies or functions described herein. The instructions **822** may also reside, completely or at least partially, within the main memory **804** and/or within processing logic **826** of the processing device **802** during execution thereof by the computer system **800**, the main memory **804** and the processing device **802** also constituting computer-readable media. The instructions may further be transmitted or received over a network **820** via the network interface device **808**.

While the computer-readable storage medium **828** is shown in an exemplary embodiment to be a single medium, the term “computer-readable storage medium” should be taken to include a single medium or multiple media (e.g., a centralized or distributed database, and/or associated caches and servers) that store the one or more sets of instructions. The term “computer-readable storage medium” shall also be taken to include any medium that is capable of storing, encoding or carrying a set of instructions for execution by the machine and that cause the machine to perform any one or more of the methodologies of the present invention. The term “computer-readable storage medium” shall accordingly be taken to include, but not be limited to, solid-state memories, optical media, and magnetic media.

The preceding description sets forth numerous specific details such as examples of specific systems, components, methods, and so forth, in order to provide a good understanding of several embodiments of the present invention. It will be apparent to one skilled in the art, however, that at least some embodiments of the present invention may be practiced without these specific details. In other instances, well-known components or methods are not described in detail or are presented in simple block diagram format in order to avoid unnecessarily obscuring the present invention. Thus, the specific details set forth are merely exemplary. Particular implementations may vary from these exemplary details and still be contemplated to be within the scope of the present invention.

In the above description, numerous details are set forth. It will be apparent, however, to one of ordinary skill in the art having the benefit of this disclosure, that embodiments of the invention may be practiced without these specific details. In some instances, well-known structures and devices are shown in block diagram form, rather than in detail, in order to avoid obscuring the description.

Some portions of the detailed description are presented in terms of algorithms and symbolic representations of operations on data bits within a computer memory. These algorithmic descriptions and representations are the means used by those skilled in the data processing arts to most effectively convey the substance of their work to others skilled in the art. An algorithm is here, and generally, conceived to be a self-consistent sequence of steps leading to a desired result. The steps are those requiring physical manipulations of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or magnetic signals capable of being stored, transferred, combined, compared, and otherwise manipulated. It has proven convenient at times, princi-

14

pally for reasons of common usage, to refer to these signals as bits, values, elements, symbols, characters, terms, numbers, or the like.

It should be borne in mind, however, that all of these and similar terms are to be associated with the appropriate physical quantities and are merely convenient labels applied to these quantities. Unless specifically stated otherwise as apparent from the above discussion, it is appreciated that throughout the description, discussions utilizing terms such as “determining”, “identifying”, “adding”, “selecting” or the like, refer to the actions and processes of a computer system, or similar electronic computing device, that manipulates and transforms data represented as physical (e.g., electronic) quantities within the computer system’s registers and memories into other data similarly represented as physical quantities within the computer system memories or registers or other such information storage, transmission or display devices.

Embodiments of the invention also relate to an apparatus for performing the operations herein. This apparatus may be specially constructed for the required purposes, or it may comprise a general purpose computer selectively activated or reconfigured by a computer program stored in the computer. Such a computer program may be stored in a computer readable storage medium, such as, but not limited to, any type of disk including floppy disks, optical disks, CD-ROMs, and magnetic-optical disks, read-only memories (ROMs), random access memories (RAMs), EPROMs, EEPROMs, magnetic or optical cards, or any type of media suitable for storing electronic instructions.

The algorithms and displays presented herein are not inherently related to any particular computer or other apparatus. Various general purpose systems may be used with programs in accordance with the teachings herein, or it may prove convenient to construct a more specialized apparatus to perform the required method steps. The required structure for a variety of these systems will appear from the description below. In addition, the present invention is not described with reference to any particular programming language. It will be appreciated that a variety of programming languages may be used to implement the teachings of the invention as described herein.

It is to be understood that the above description is intended to be illustrative, and not restrictive. Many other embodiments will be apparent to those of skill in the art upon reading and understanding the above description. The scope of the invention should, therefore, be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled.

What is claimed is:

1. A method comprising:

receiving, by a processing device, an indication of a location of a misplaced item bin within a materials handling facility, the materials handling facility comprising a plurality of bins, the plurality of bins comprising the misplaced item bin and a plurality of item storage bins;

receiving, by the processing device, an indication of a misplaced item, the misplaced item having been inadvertently removed from one of the plurality of item storage bins and placed in the misplaced item bin;

identifying, by the processing device, a group of potential item storage bins for storage of the misplaced item, wherein each potential item storage bin in the group is located within a threshold distance of the location of the misplaced item bin, wherein a virtual inventory of the materials handling facility indicates that each potential

15

item storage bin in the group comprises one or more items having a same item type as the misplaced item; determining, by the processing device, an ordered list of potential item storage bins from the group of potential bins, wherein the potential item storage bins on the ordered list are arranged in an order configured to optimize a transit time between the potential item storage bins in the materials handling facility for a materials handling facility associate to store the misplaced item; and

providing, by the processing device, the ordered list to a client device corresponding to the materials handling facility associate.

2. The method of claim 1, further comprising:

receiving a result of an inspection of one of the potential item storage bins on the ordered list by the materials handling facility associate, wherein the inspection comprises comparing an actual number of items having the same item type as the misplaced item that are present in the potential item storage bin to a number of items indicated in the virtual inventory for the potential item storage bin; and

if the actual number of items does not match the number of items indicated in the virtual inventory, dynamically updating the ordered list of potential item storage bins and providing the updated ordered list to the client device.

3. The method of claim 1, further comprising:

assigning a bin weighting value to each of the potential item storage bins based at least in part on at least one of a bin location density of the potential item storage bin, a bin population density of the potential item storage bin and a last potential item storage bin inspected by the materials handling facility associate.

4. The method of claim 3, wherein determining the ordered list comprises ranking the potential item storage bins based at least in part on the respective bin weighting values.

5. A system comprising:

a memory configured to store a misplaced item service; and a processing device operatively coupled to the memory, the processing device to execute the misplaced item service configured to:

identify a plurality of inventory storage locations in a materials handling facility for storage of a misplaced item; and

determine an ordered list of the plurality of inventory storage locations, wherein the inventory storage locations are arranged in the ordered list based at least in part on at least one of a location density of the inventory storage locations, a population density of the inventory storage locations and a last inventory storage location inspected.

6. The system of claim 5, wherein the misplaced item service is further configured to:

receive an indication of a misplaced item storage location within the materials handling facility; and

receive an indication of the misplaced item, the misplaced item having been inadvertently removed from one of the plurality of inventory storage locations in the materials handling facility and placed in the misplaced item storage location.

7. The system of claim 6, wherein to identify the plurality of inventory storage locations, the misplaced item service is further configured to:

identify a plurality of inventory storage locations for which a virtual inventory of the materials handling facility

16

indicates a presence of one or more items having a same item type as the misplaced item;

determine a distance between the misplaced item storage location and each of the plurality of inventory storage locations; and

compare the distance between the misplaced item storage location and each of the plurality of inventory storage locations to a first threshold distance.

8. The system of claim 5, wherein the location density of the inventory storage locations comprises a number of other inventory storage locations located in proximity to each of the inventory storage locations.

9. The system of claim 5, wherein the population density of the inventory storage locations comprises a number of items having a same item type as the misplaced item that are present in each of the inventory storage locations.

10. The system of claim 5, wherein a last inventory storage location inspected comprises one of the plurality of inventory storage locations inspected most recently by a materials handling facility associate prior to the ordered list being determined.

11. The system of claim 5, wherein to determine the ordered list of the plurality of inventory storage locations, the misplaced item service is further configured to:

assign a weighting value to each of the plurality of inventory storage locations based at least in part on at least one of the location density of the inventory storage locations, the population density of the inventory storage locations and the last inventory storage location inspected; and rank the plurality of inventory storage locations in the ordered list based at least in part on the respective weighting values.

12. The system of claim 5, wherein the misplaced item service is further configured to:

receive a result of an inspection of one of the plurality of inventory storage locations on the ordered list by a materials handling facility associate, wherein the inspection comprises comparing an actual number of items having a same item type as the misplaced item that are present in the inventory storage location to a number of items indicated in a virtual inventory for the inventory storage location; and

if the actual number of items does not match the number of items indicated in the virtual inventory, dynamically updating the ordered list of inventory storage locations and providing the updated ordered list to a client device.

13. A non-transitory computer-readable storage medium storing instructions which, when executed, cause a processing device to perform operations comprising:

receiving, by the processing device, an indication of a location of a misplaced item bin within a materials handling facility;

receiving, by the processing device, an indication of a misplaced item;

identifying, by the processing device, a group of potential item storage bins for storage of the misplaced item, wherein each potential item storage bin in the group is located within a threshold distance of the location of the misplaced item bin;

determining, by the processing device, an ordered list of potential item storage bins from the group of potential bins, wherein the potential item storage bins on the ordered list are arranged at least in part according to weighting values representing a likelihood that the misplaced item belongs to the potential item storage bins; and

17

providing, by the processing device, the ordered list to a client device corresponding to a materials handling facility associate.

14. The non-transitory computer-readable storage medium of claim 13, wherein the materials handling facility comprises a plurality of bins, the plurality of bins comprising the misplaced item bin and a plurality of item storage bins.

15. The non-transitory computer-readable storage medium of claim 14, wherein the misplaced item has been inadvertently removed from one of the plurality of item storage bins and placed in the misplaced item bin.

16. The non-transitory computer-readable storage medium of claim 13, wherein a virtual inventory of the materials handling facility indicates that each potential item storage bin in the group comprises one or more items having a same item type as the misplaced item.

17. The non-transitory computer-readable storage medium of claim 13, wherein the potential item storage bins on the ordered list are arranged in an order configured to optimize a transit time between the potential item storage bins in the materials handling facility for the materials handling facility associate.

18. The non-transitory computer-readable storage medium of claim 13, wherein the operations further comprise:

18

assigning a bin weighting value to each of the potential item storage bins based at least in part on at least one of a bin location density of the potential item storage bin, a bin population density of the potential item storage bin and a last potential item storage bin inspected by the materials handling facility associate; and

ranking the potential item storage bins in the ordered list based at least in part on the respective bin weighting values.

19. The non-transitory computer-readable storage medium of claim 18, wherein the bin location density of the potential item storage bin comprises a number of other potential item storage bins located in proximity to each of the potential item storage bins, and wherein the bin population density of the potential item storage bin comprises a number of items having a same item type as the misplaced item that are present in each of the potential inventory storage bins.

20. The non-transitory computer-readable storage medium of claim 18, wherein the last potential item storage bin inspected by the materials handling facility associate comprises one of the plurality of potential item storage bins inspected most recently by the materials handling facility associate prior to the ordered list being determined.
